ABSTRACT

Brain surface conformal mapping has been studied intensively. In this paper, we propose a method that computes a conformal mapping from a multiply connected mesh to the so-called *slit domain*, which consists of a canonical rectangle or disk in which 3D curved landmarks on the original surfaces are mapped to concentric or parallel lines in the slit domain. After cutting along some landmark curve features on surface models of the cerebral cortex, we obtain multiple connected domains. By computing exact harmonic one-forms, closed harmonic one-forms, and holomorphic one-forms, we are able to build a circular slit mapping that conformally maps the surface to an annulus with some concentric arcs and a rectangle with some slits. The whole algorithm is based on solving linear systems so it is very stable. In the slit domain parameterization results, the feature curves are either mapped to straight lines or a concentric arcs. This representation is convenient for anatomical visualization, and may assist statistical comparisons of anatomy, surface-based registration and signal processing. Preliminary experimental results parameterizing various brain anatomical surfaces are presented.

Index Terms— Biomedical Imaging, Brain Mapping, Surface Parameterization, Slit Mapping

1. INTRODUCTION

Parameterization of anatomical surfaces in brain imaging is valuable to help analyze anatomical shape and statistically combine or compare 3D anatomical models across subjects. Conformal parameterization can provide a one-to-one, onto, and angle-preserving map from a general manifold to a canonical space, such as a sphere, disk or other subregion of the plane. In this mapping, the elements of the first fundamental form remain unchanged, except for a scaling

This work was funded by the National Institutes of Health through the NIH Roadmap for Medical Research, Grant U54 RR021813 entitled Center for Computational Biology (CCB). The work was performed while the third author was on leave at the National Science Foundation as Assistant Director of the Directorate for Mathematics & Physical Sciences.

factor. The mapping preserves similarities in small regions; it can also be used to simplify covariant derivative formulas on a general manifold, which is useful for solving variational problems on surfaces, such as signal denoising or computation of correspondence vector fields that match different surfaces.

In this paper, we introduce a new method to conformally map a multiply connected domain to an annulus with multiple concentric arcs (called the *circular slit map*) or to a rectangle with multiple straight lines (the *parallel slit map*). It is a global conformal parameterization method without segmentation. First, it computes exact harmonic one-forms and closed harmonic one-forms. Secondly, it computes all bases of holomorphic one-forms. Given appropriate boundary conditions, it can compute a unique circular slit map up to a rotation around the center. The slit mapping computes the intrinsic structure of the given surface, which can be reflected in the shape of the target domain.

This work continues our group's previous research on brain surface conformal parameterization. The new work has the same motivation, i.e., to match brain landmarks along boundaries by global conformal parameterization, but it overcomes the singularity problem in the holomorphic flow segmentation algorithm [1]. The method is also more stable than the highly non-linear solution of the Ricci flow method [2].

1.1. Related Work

Brain surface parameterization has been studied intensively. Schwartz et al. [3], and Timsari and Leahy [4] computed quasi-isometric flat maps of the cerebral cortex. Drury et al. [5] presented a multiresolution method for flattening the cerebral cortex. Hurdal and Stephenson [6] reported a discrete mapping approach that uses circle packings to produce "flattened" images of cortical surfaces on the sphere, the Euclidean plane, and the hyperbolic plane. The maps obtained are quasi-conformal approximations of classical conformal maps. Haker et al. [7] implemented a finite element approximation for parameterizing brain surfaces via conformal mappings. They select a point on the cortex to map to the

north pole of the Riemann sphere and conformally map the rest of the cortical surface to the complex plane by stereographic projection of the Riemann sphere to the complex plane. Gu et al. [8] proposed a method to find a unique conformal mapping between any two genus zero manifolds by minimizing the harmonic energy of the map. They demonstrate this method by conformally mapping a cortical surface to a sphere. Ju et al. [9] presented a least squares conformal mapping method for cortical surface flattening. Joshi et al. [10] proposed a scheme to parameterize the surface of the cerebral cortex by minimizing an energy functional in the p^{th} norm. Wang et al. [1] have used holomorphic 1-forms to parameterize anatomical surfaces with complex (possibly branching) topology. Wang et al. [2] introduced a brain surface conformal mapping algorithm based on algebraic functions. By solving the Yamabe equation with the Ricci flow method, it can conformally map a brain surface to a multi-hole disk. Recently, Ju et al. [11] reported the results of a quantitative comparison of FreeSurfer [12], CirclePack, and least squares conformal mapping (LSCM) with respect to geometric distortion and computational speed.

2. THEORETICAL BACKGROUND

Suppose S is a surface embedded in \mathbb{R}^3 , with induced Euclidean metric \mathbf{g} . S is covered by an atlas $\{(U_\alpha, \phi_\alpha)\}$. Suppose (x_α, y_α) is the local parameter on the chart (U_α, ϕ_α) . We say (x_α, y_α) is *isothermal*, if the metric has the representation $\mathbf{g} = e^{2\lambda(x_\alpha, y_\alpha)}(dx_\alpha^2 + dy_\alpha^2)$.

The *Laplace-Beltrami operator* is defined as $\Delta_{\mathbf{g}} = \frac{1}{e^{2\lambda(x_\alpha, y_\alpha)}}(\frac{\partial^2}{\partial x_\alpha^2} + \frac{\partial^2}{\partial y_\alpha^2})$. A function $f : S \rightarrow \mathbb{R}$ is *harmonic*, if $\Delta_{\mathbf{g}} f \equiv 0$.

Suppose ω is a differential one-form with the representation $f_\alpha dx_\alpha + g_\alpha dy_\alpha$ in the local parameters (x_α, y_α) , and $f_\beta dx_\beta + g_\beta dy_\beta$ in the local parameters (x_β, y_β) . Then

$$\begin{pmatrix} \frac{\partial x_\alpha}{\partial x_\beta} & \frac{\partial y_\alpha}{\partial x_\beta} \\ \frac{\partial x_\alpha}{\partial y_\beta} & \frac{\partial y_\alpha}{\partial y_\beta} \end{pmatrix} \begin{pmatrix} f_\alpha \\ g_\alpha \end{pmatrix} = \begin{pmatrix} f_\beta \\ g_\beta \end{pmatrix}.$$

ω is a *closed one-form*, if on each chart (x_α, y_α) , $\frac{\partial f}{\partial y_\alpha} - \frac{\partial g}{\partial x_\alpha} = 0$. ω is an *exact one-form*, if it equals the gradient of some function. An exact one-form is also a closed one-form. If a closed one-form ω satisfies $\frac{\partial f}{\partial x_\alpha} + \frac{\partial g}{\partial y_\alpha} = 0$, then ω is a *harmonic one-form*. The gradient of a harmonic function is an exact harmonic one-form.

The so-called *Hodge star operator* turns a one-form ω to its *conjugate* $^*\omega$, $^*\omega = -g_\alpha dx_\alpha + f_\alpha dy_\alpha$.

A *holomorphic one-form* is a complex differential form $\omega + \sqrt{-1}^*\omega$, where ω is a harmonic one-form.

Suppose S is an open surface with n boundaries $\gamma_1, \dots, \gamma_n$. We can uniquely find a holomorphic one-form ω , such that

$$\int_{\gamma_k} \omega = \begin{cases} 2\pi & k = 1 \\ -2\pi & k = 2 \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

Circular Slit Mapping Fix a point p_0 on the surface, for any point $p \in S$, let γ be an arbitrary path connection p_0 and p , then the circular slit mapping is defined as $\phi(p) = e^{\int_\gamma \omega}$.

Theorem 2.1 *The function ϕ effects a one-to-one conformal mapping of M onto the annulus $1 < |z| < e^{\lambda_0}$ minus $n - 2$ concentric arcs situated on the circles $|z| = e^{\lambda_i}, i = 1, 2, \dots, n - 2$.*

The proof of the above theorem on slit mapping can be found in [13]. For a given choice of the inner and outer circle, the circular slit mapping is uniquely determined up to a rotation around the center. The parallel slit mapping can be defined in a similar way.

Parallel Slit Mapping Let \bar{S} be the universal covering space of the surface S , $\pi : \bar{S} \rightarrow S$ be the projection and $\bar{\omega} = \pi^*\omega$ be the pull back of ω . Fix a point \bar{p}_0 on \bar{S} , for any point $p \in \bar{S}$, let $\bar{\gamma}$ be an arbitrary path connection \bar{p}_0 and \bar{p} , then the parallel slit mapping is defined as $\bar{\phi}(\bar{p}) = \int_{\bar{\gamma}} \bar{\omega}$.

3. ALGORITHM PIPELINE

Suppose the input mesh has $n + 1$ boundaries, $\partial M = \gamma_0 - \gamma_1 - \dots - \gamma_n$. Without loss of generality, we map γ_0 to the outer circle of the circular slit domain, γ_1 to the inner circle, and all the others to the concentric slits.

The algorithm pipeline is as follows :

- 1 Compute the basis for all exact harmonic one-forms;
2. Compute the basis for all closed harmonic one-forms;
3. Compute the basis for all holomorphic one-forms;
4. Construct the slit mapping.

3.1. Basis for Exact Harmonic One-forms

The first step of the algorithm is to compute the basis for exact harmonic one-forms. Let γ_k be an inner boundary, we compute a harmonic function $f_k : S \rightarrow \mathbb{R}$ by solving the following Dirichlet problem on the mesh M : $\begin{cases} \Delta f_k \equiv 0 \\ f_k|_{\gamma_j} = \delta_{kj} \end{cases}$, where δ_{kj} is the Kronecker function, Δ is the discrete Laplace-Beltrami operator using the co-tangent formula proposed in [14].

The exact harmonic one-form η_k can be computed as the gradient of the harmonic function f_k , $\eta_k = df_k$, and $\{\eta_1, \eta_2, \dots, \eta_n\}$ form the basis for the exact harmonic one-forms .

3.2. Basis for Harmonic One-forms

After getting the exact harmonic one-forms, we will compute the closed one-form basis. Let γ_k ($k > 0$) be an inner boundary. Compute a path from γ_k to γ_0 , denote it as ζ_k . ζ_k cut the mesh open to M_k , while ζ_k itself is split into two boundary segments ζ_k^+ and ζ_k^- in M_k . Define a function $g_k : M_k \rightarrow \mathbb{R}$

by solving a Dirichlet problem, $\begin{cases} \Delta g_k \equiv 0 \\ g_k|_{\zeta_k^+} = 1 \\ g_k|_{\zeta_k^-} = 0. \end{cases}$ Compute

the gradient of g_k and let $\tau_k = dg_k$, then map τ_k back to M , where τ_k becomes a closed one-form. Then we need to find a function $h_k : M \rightarrow \mathbb{R}$, by solving the following linear system: $\Delta(\tau_k + dh_k) \equiv 0$.

Updating τ_k to $\tau_k + dh_k$, we now have $\{\tau_1, \tau_2, \dots, \tau_n\}$ as a basis set for all the closed but non-exact harmonic one-forms.

With both the exact harmonic one-form basis and the closed non-exact harmonic one-form basis computed, we can construct the harmonic one-form basis by taking the union of them: $\{\eta_1, \eta_2, \dots, \eta_n, \tau_1, \tau_2, \dots, \tau_n\}$.

3.3. Basis for Holomorphic One-forms

In Step 1 we computed the basis for exact harmonic one-forms $\{\eta_1, \dots, \eta_n\}$. Now we compute their conjugate one-forms $\{*\eta_1, \dots, *\eta_n\}$, so that we can combine all of them together into a holomorphic one-form basis set.

First of all, for η_k we compute an initial approximation η'_k by a brute-force method using the Hodge star. That is, rotating η_k by 90° about the surface normal to obtain η'_k . In practice such an initial approximation is usually not accurate enough. In order to improve the accuracy, we employ a technique utilizing the harmonic one-form basis we just computed. From the fact the η_k is harmonic, we can conclude that its conjugate $*\eta_k$ should also be harmonic. Therefore, $*\eta_k$ can be represented as a linear combination of the base harmonic one-forms: $*\eta_k = \sum_{i=1}^n a_i \eta_i + \sum_{i=1}^n b_i \tau_i$.

Using the wedge product \wedge , we can construct the following linear system, $\int_M *\eta_k \wedge \eta_i = \int_M \eta'_k \wedge \eta_i, \int_M *\eta_k \wedge \tau_j = \int_M \eta'_k \wedge \tau_j$.

We solve this linear system to obtain the coefficients a_i and b_i ($i = 1, 2, \dots, n$) for the conjugate one-form $*\eta_k$. Pairing each base exact harmonic one-form in the basis with its conjugate, we get a basis set for the holomorphic one-form group on M : $\{\eta_1 + \sqrt{-1}*\eta_1, \dots, \eta_n + \sqrt{-1}*\eta_n\}$

3.4. Construct Slit Mapping

After computing the holomorphic one-form basis, we need to find a special holomorphic one-form $\omega = \sum_{i=1}^n \lambda_i (\eta_i + \sqrt{-1}*\eta_i)$, such that the imaginary part of its integral satisfies

$$Im \left(\int_{\gamma_k} \omega \right) = \begin{cases} -2\pi & k = 1 \\ 0 & k > 1 \end{cases}$$

To get the coefficients λ_i , we solve the following linear system for $\lambda_i, i = 1, \dots, n$:

$$\begin{pmatrix} \alpha_{11} & \alpha_{12} & \cdots & \alpha_{1n} \\ \alpha_{21} & \alpha_{22} & \cdots & \alpha_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \alpha_{n1} & \alpha_{n2} & \cdots & \alpha_{nn} \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \\ \vdots \\ \lambda_n \end{pmatrix} = \begin{pmatrix} -2\pi \\ 0 \\ \vdots \\ 0 \end{pmatrix}$$

where $\alpha_{kj} = \int_{\gamma_j} *\eta_k$.

It can be proven that this linear system has a unique solution, which reflects the fact that γ_1 is mapped to the inner circle of the circular slit domain. Further, the system implies the following equation $\lambda_1 \alpha_{01} + \lambda_2 \alpha_{02} + \dots + \lambda_n \alpha_{0n} = 2\pi$, which means that γ_0 is mapped to the outer circle in the circular slit domain.

After computing the desired holomorphic one-form ω , we are ready to generate the circular slit mapping. What we need to compute is a complex-valued function $\phi : M \rightarrow \mathbb{C}$ by integrating ω and taking the exponential map. Choosing a base vertex v_0 arbitrarily, and for each vertex $v \in M$ choosing the shortest path γ from v_0 to v , we can compute the map as the following: $\phi(v) = e^{\int_{\gamma} \omega}$.

Based on the circular slit map ϕ we just computed, we can compute a parallel slit map $\tau : M \rightarrow \mathbb{C}$: $\tau(v) = \ln \phi(v)$.

4. EXPERIMENTAL RESULTS

We applied our algorithms to parameterize various anatomical surfaces extracted from 3D MRI scans of the brain. In this paper, the segmentations are regarded as given, and result from automated and manual segmentations detailed in our prior work. In Figure 1, Subfigure 1 shows an example of our computation results. For the cortical surface of the brain, we cut it open along six major landmarks. (a) and (b) show the brain surface from two different views. With our slit mapping algorithm, we can conformally map it to a rectangular domain with four slits (c) and an annulus with four concentric arcs (d). (d) and (e) demonstrate the conformal texture mapping as the pull-back of the coordinates induced by the circular slit map of (f).

We also tested our algorithm on a left hippocampal surface, a key structure in the medial temporal lobe of the brain, for which parametric shape models are commonly developed for tracking shape differences and longitudinal atrophy in disease. The results are shown in the first row of Subfigure 2 in Figure 1. We leave two holes on the front and back of the hippocampal surface, representing its anterior junction with the amygdala and its posterior limit as it turns into the white matter of the *fornix*. We also randomly selected two curves lying in regions of high curvature, which are of interest for surface registration research (these could also be boundaries of the CA fields, or other architectonic boundaries, if high-field images are available). The parallel slit map result is shown with appropriate landmark curves labeled. We also applied our algorithm to lateral ventricular surface (second row in Subfigure 2 of Figure 1). We introduced three cuts. The motivation for these cuts are based on the topology of the lateral ventricles, in which several horns are joined together at the ‘‘atrium’’ or ‘‘trigone’’. In the parallel slit map result, two boundaries are mapped to left and right boundaries, respectively. The rectangle’s lengthy aspect ratio reflects its intrinsically long horn-like shape.

In Figure 1, Subfigure 3 demonstrates various parallel slit map results given different boundary conditions. As shown in Subfigure 3, four landmarks were cut open. After the cut, the surface turns into an open boundary genus three surface. For the Equation 1, we selected two different pairs of landmarks as the exterior and inner boundaries by putting the integration of different γ_k as 2π and -2π . The second column shows the parameterization results when we use landmark a and d as the exterior and inner circular boundaries, respectively. The third column shows the parameterization results when we select the other pair of landmark curves as the boundary conditions.

5. CONCLUSIONS AND FUTURE WORK

In this paper, we presented a brain surface conformal parameterization method based on the slit map, which transfers cortical geometry and any embedded landmarks into a canonical domain, with conformal coordinates. With fixed boundary conditions, our algorithm can compute unique circular slit maps and parallel slit maps, where the positions and lengths of the slits are determined by the conformal equivalence class of the surface. We tested our algorithm on hippocampal, lateral ventricular and cerebral cortical surfaces. Compared with our previous work [1, 2], our new work does not have any singularities and more stable because only linear systems are involved. Another advantage is that mappings between surfaces could be readily set up via 2D matching in these domains, using the conformal parameterization to conveniently discretize differential operators. Our future work will include empirical application of the slit map algorithm to biomedical applications in computational anatomy, including the detection of population differences and the tracking of brain change over time.
